Parameter

A **parameter** is a **global placeholder** value such as a number, date, or string that can replace a constant value in a calculation, filter or reference line.

For example, you may create a calculated field that returns True is Sales is greater than \$500,000 and otherwise returns False. You can replace the constant value “500,000” in the formula with a parameter. Then, using the parameter control, you can dynamically change the threshold in your calculation.
